What is Android?

- Android is a multi-user, **Linux-based OS** developed by Google and the Open Handset Alliance
- primarily designed for touchscreen mobile devices based on **direct manipulation** by the user
- the Android code is **open source**, released under the Apache License (freely modifiable)
- comes with some standard smartphone applications
- the Android SDK offers free developer tools, API libraries, and an IDE (IntelliJ based)
- allows for simple application (app)
 development using customized Java

- Q2 2016: Android has become **the world's most popular smartphone platform** with a market share of 86,2% (excluding, US, Australia, and Japan)
- is deployed on tv-sets, games consoles, digital cameras, watches, ...

OS	Q2 2016 Market

Android basics – System architecture (until 5.0)

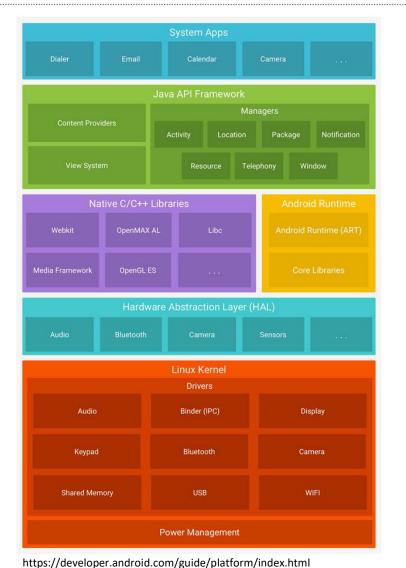

http://en.wikipedia.org/wiki/Android_(operating_system)

Prof. Dr. C. Linnhoff-Popien, Michael Beck, André Ebert - Praktikum Mobile und Verteilte Systeme

Android System Architecture (since 5.0)

- Android System is Open Source: own interfaces and enhancements may be provided
- E.g., HAL modules can be defined in hardware.h

typedef struct camera_module {
 hw_module_t common;
 int (*get_number_of_cameras)(void);
 int (*get_camera_info)(int camera_id, struct camera_info *info);
} camera_module_t;

 Abstraction of high-level application development and lower-level hardware programming (drivers, etc.)

Prof. Dr. C. Linnhoff-Popien, Michael Beck, André Ebert - Praktikum Mobile und Verteilte Systeme

Android basics – Dalvik Virtual Machine vs. ART

- Java code is typically compiled into Bytecode
- At runtime, a Virtual Machine translates this code into machine code
 - e.g., Java Virtual Machine (JVM) on Desktop PCs (stack-based)
- Android, however, uses the Android Runtime (ART)
 - Replaces Dalvik VM **since version 5.0** (backward compatible)
 - All Apps running within own processes and own ART-instance (→ multiple virtual machines)
 - Transformes Bytecode directly to binary code upon installation
 - Faster execution, improved garbage collection and memory allocation
 - 64-Bit support
 - Apps are stored compiled

Android basics – Security

- Android implements the **principle of least privilege** for its apps
- Each Android app resides in its own kernel-level security sandbox:
 - each application is a different user
 - access permissions for all of an application's files are based on the Linux user ID
 - every application runs in its own Linux process
 - each process has its own VM (adds to stability)
- Apps can request **permission to access device data and services**, such as user's contacts, SMS messages, SD card, camera, internet, ...
- All application permissions must be **requested by the developer** in the app's Manifest file and granted by the user

developer-8-step-checkup.html

Android process and memory management

- Android employs real application multi-tasking, optimized for a mobile usage pattern
- Requirements:
 - apps should appear "always running"
 - − no swap space → hard limits on memory usage
 - app switching in less than 1 second
- Implementation:
 - LRU list of running apps with preferences
 - when memory gets low, Android kills the least important process
 - Bundle class can be used for saving application state
 - developers have to take care of correctly saving an instance's state

Android application threads

- Every application is initiated with a single main thread (**UIThread**)
- If time-consuming tasks are performed on the main thread, the UI blocks
 - leads to ANR dialog after 5 seconds
 - instead, extra worker threads should be used
- the Android UI toolkit is not thread-safe and hence must not be manipulated from a worker thread

<u>Rules:</u>

1) Do not block the UI thread!

2) Do not access the Android UI toolkit from outside the UI thread!

• Recommendation: use the Handler-, Java Thread-, Loaderand AsyncTask-classes

Android application components

- Android apps might consist of several different building blocks
 - Activities
 - Fragments
 - Loaders
 - Services
 - Content Providers
 - Broadcast Receivers

http://developer.android.com/guide/components/index.html

- Each component performs different tasks
- Each component has its own distinct **lifecycle** that you have to take care of as a developer in order to keep your app stable

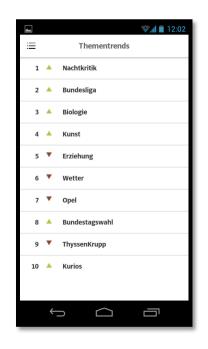

Activities

- Implemented as a subclass of android.app.Activity
- An activity represents a single screen with a user interface
- Started on App start or by firing Intents
 - typically defined in XML, not in code
 - Model-View-Controller (MVC) pattern

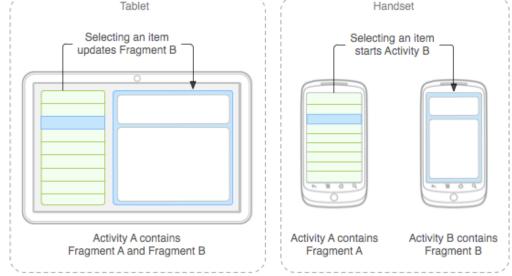

Prof. Dr. C. Linnhoff-Popien, Michael Beck, André Ebert - Praktikum Mobile und Verteilte Systeme

Fragments

- represent a UI portion of an Activity (i.e., a "subactivity")
- can be combined in a single activity to build multi-pane UIs, but cannot stand alone
- enable the reuse of code in multiple activities
- have their own lifecycle, too, but based on the host Activity's current state
- can be managed in the Activity back stack

- different fragment combinations for different screen sizes
 - e.g., in order to support both tablets and phones, different layout configs can be used to make optimal use of the available screen space

Prof. Dr. C. Linnhoff-Popien, Michael Beck, André Ebert - Praktikum Mobile und Verteilte Systeme SS 2017 Android-Basics

Loaders

- Introduced in Android 3.0 (API Level 11)
- Used to load data from a **Content Provider**
- Avoid a lack of responsiveness due to performing slow queries on the UI thread
- Loaders are using **separate threads**
- Thread management is simplified by providing **callbacks** in case of occurring events
- Results may be **cached**, even across configuration changes
- Loaders may monitor data sources and underlying data in order to react to changes

Services

- Java class implemented as a subclass of android.app.Service
- running in the background (without direct user interaction)
- intended for **long-running operations**, e.g. playing music, fetching network data
- can be started (and stopped) from an Activity
 - in order to interact with a Service, an Activity can "bind" to it
- Services can request being considered **foreground** (*"*please dont kill me")
 - indicated by an icon in the status bar to create user awareness
- a process running a service is ranked higher than a process with background activities (and is hence less likely to be killed)

BroadcastReceivers

- implemented as a subclass of BroadcastReceiver
- each broadcast is delivered as an Intent object
- respond to system-wide broadcast announcements:
 - screen turned off
 - battery status
 - picture captured
 - custom broadcasts
- do not display a user interface
- usually, a broadcast receiver is just a gateway to other app components,
 e.g., by starting an Activity or Service upon a certain event

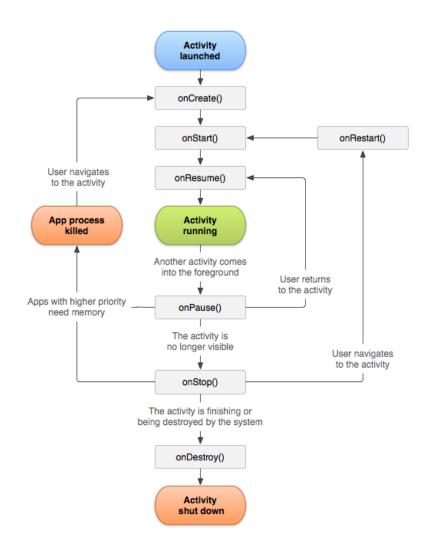

ContentProviders

- implemented as a subclass of ContentProvider
- must implement a standard set of APIs enabling other applications to perform transactions (CRUD operations) on the app's information
- manages shared application data, stored in files, SQLite databases, on the web, ...
- can also be used internally by an App for storing/retrieving private information
- Examples: Android contact information / Android MediaStore / etc.
 - any application (given it has the right permissions) is able to query this content provider to read or modify contact information

Activity lifecycle management

- crucial for developing strong and flexible applications
- An activity can exist in essentially three states:
 - Resumed

The activity is in the foreground of the screen and has user focus

- Paused

Another activity is in the foreground and has focus, but this one is still visible

Stopped

The activity is completely obscured by another activity (i.e., in the background)

Android Manifest

- Each application must have an AndroidManifest.xml file
- The manifest file **must declare**
 - an app's Java package name
 - all of an app's components (activities, services, ...)
 - all of the app's requirements (min. Android version, hardware, ...)
- and might also declare
 - intent filters (for implicit intents)
 - custom permissions
 - used libraries (apart from the standard Android lib)
 - required permissions

- ..

Android permissions

- by default, no app is allowed to perform any protected operations
- the **permission mechanism** can be used for a (moderately) fine-grained control of what features an app can access
 - internet, camera, SMS, contacts, reboot, ...
- at install time, a user has to accept the requested permissions (do-or-die)
- since Android 4.3, there's a (hidden) functionality to withdraw individual permissions
- Since Android 6.0, it is possible to install Apps without granting all permissions
- custom permissions can be defined, controlling...
 - from which apps broadcasts might be received
 - who is allowed to start an activity or a service

Android resources

- all types of non-code resources (images, strings, layout files, etc.) should be managed externally
 - allowing customized alternatives for each special use-case (different strings for different languages, customized layouts for different screen sizes)
 - requires each resource to have a unique resource id, which is generated automatically
- resource types:
 - Bitmap / Drawable files (res/drawable, res/mimap-hdpi...)
 - XML layout files (res/layout)
 - string literals and value arrays (res/values)
- alternatives are provided in separate folders:
 <resource_name>-<qualifier1[-qualifier2]>

R.java???

- when compiling your project, a class called R.java is generated
 - contains subclasses for each type of resources and IDs
- resources provided externally can be accessed in code using the projects R class and the corresponding resource's type and ID
- a resource ID is composed of
 - the resource type (e.g., string)
 - the resource name (filename or XML attribute "name")
- Resources can be accessed in code: getString (R.string.<resource-name>) and in XML: @string/<resource-name>
- (<Classcast>) findViewById(R.layout.<layout-name>)

Rules: Never touch R.java! Never import android.R!

Google Services

https://developer.android.com/google/index.html

- Google offers app developers a number of handy services and APIS that may be integrated
- these services, however, are not part of the Android platform
 - Google Cloud Messaging Service allows developers to send push notification to their users

Google Location Services

offer utilities for painlessly building location based services (LBS)

– Google+

allows authentication, social graph interactions, etc.

Google Maps, Google Play Services, ...

Android platform tools

- The Android Developer Tools (ADT) contain a variety of useful tools for application programming, debugging and publishing
 - SDK Manager
 - ADB (Android Debug Bridge)
 - devices
 - shell
 - push/pull
 - install/uninstall
 - logcat
 - DX
 - converts .class files into .dex format
 - DEXDUMP
 - Android Device Emulator / AVD Manager
 - GUI Builder
 - DDMS (standalone, e.g., for resource usage monitoring)
