Context-Awareness and Location-based Services

Prof. Dr. Claudia Linnhoff-Popien
Philipp Marcus, Mirco Schönfeld
<http://www.mobile.ifi.lmu.de>

Sommersemester 2015

Context-Awareness and Location-based Services

Today:

- Context-Awareness
 - What is Context / Context-Awareness?
 - How to sense context?
- LBS
 - What are LBS?
 - Origin and evolution of LBS
 - Classification and role model
 - Position Management in LBS

Next week:

- Concept presentations

Context-Awareness

“Context-aware computing is a mobile computing paradigm in which applications can discover and take advantage of contextual information (such as user location, time of day, nearby people and devices, and user activity).” (Chen/Kotz 2000)

Defining Context

- **Schilit (1994):**
 - *Computing context*: connectivity, communication cost, bandwidth, nearby resources (printers, displays, PCs)...
 - *User context*: user profile, location, nearby people, social situation, activity, mood ...
 - *Physical context*: temperature, lighting, noise, traffic conditions
 - **Chen/Kotz (2000)** added:
 - *Time context* (time of day, week, month, year...)
- **Dey and Abowd (2000):** “Context is any information that can be used to characterize the situation of an entity. An entity is a person, place, or object that is considered relevant to the interaction between a user and an application, including the user and the application themselves.”

Sensing Context

- Sensing location: e.g. GPS (cf. outdoor / indoor positioning)
- Media capturing: e.g. camera, microphone
- Connectivity: mobile network, bluetooth, WLAN, NFC
- Time: e.g. day of week, calendar
- Motion and environmental sensors:
`TYPE_ACCELEROMETER, TYPE_AMBIENT_TEMPERATURE,`
`TYPE_GRAVITY, TYPE_GYROSCOPE, TYPE_LIGHT,`
`TYPE_LINEAR_ACCELERATION, TYPE_MAGNETIC_FIELD,`
`TYPE_ORIENTATION, TYPE_PRESSURE, TYPE_PROXIMITY,`
`TYPE_RELATIVE_HUMIDITY, TYPE_ROTATION_VECTOR,`
`TYPE_TEMPERATURE`
- Further: active/running apps on device,
remaining energy level,
...

Example: Active Badge / ParcTab

Active Badge

- From Olivetti Research Lab in 90's
- One of the first context-aware systems
- Office personnel wear badges (IR signal)
- Applications
 - Call Forwarding

12.00 1st January 1990

ParcTab

- From Xerox Palo Alto Research Center
- Room-sized IR cells
- Applications
 - Active Map
 - Location information (Room number)
 - Others: Find local resources (e.g. nearest printer), Remote control

Example: GUIDE

- Developed in Lancaster University
 - For Lancaster City visitors
- Using WaveLAN as communication infrastructure
 - A tourist comes to a region(cell), then he receives information of the region.
- Information provided using
 - Fujitsu TeamPad 7600 portable PC
 - Java based http browser

Location-based Services: Definitions

- "[...] services that use the location of the target for **adding value** to the service."

(GSM Association: Location-based Services. Permanent Reference Document: SE.23; Version 3.1.0, Jan 2003.)

- "[...] service provided either **by teleoperator or a 3rd party service provider** that utilizes the available location information of the terminal."

3rd Generation Partnership Project: Technical Specification Group Services and System Aspects;
Functional stage 2 description of Location Services (LCS) (Release 9) TS 23.271, 2009.

- "Location-based Services (LBSs) are IT services for providing information that has been **created, compiled, selected, or filtered** taking into consideration the **current locations** of the users or those of other persons or mobile devices."

Küpper, A.: Location-based Services - Fundamentals and Operation. John Wiley and Sons, 2005.

- "A wireless-IP service that uses geographic information **to serve a mobile user**. Any application service that **exploits the position of a mobile terminal**."

Open Geospatial Consortium Inc. OpenGIS Location Services (OpenLS): Core Services, 2008.

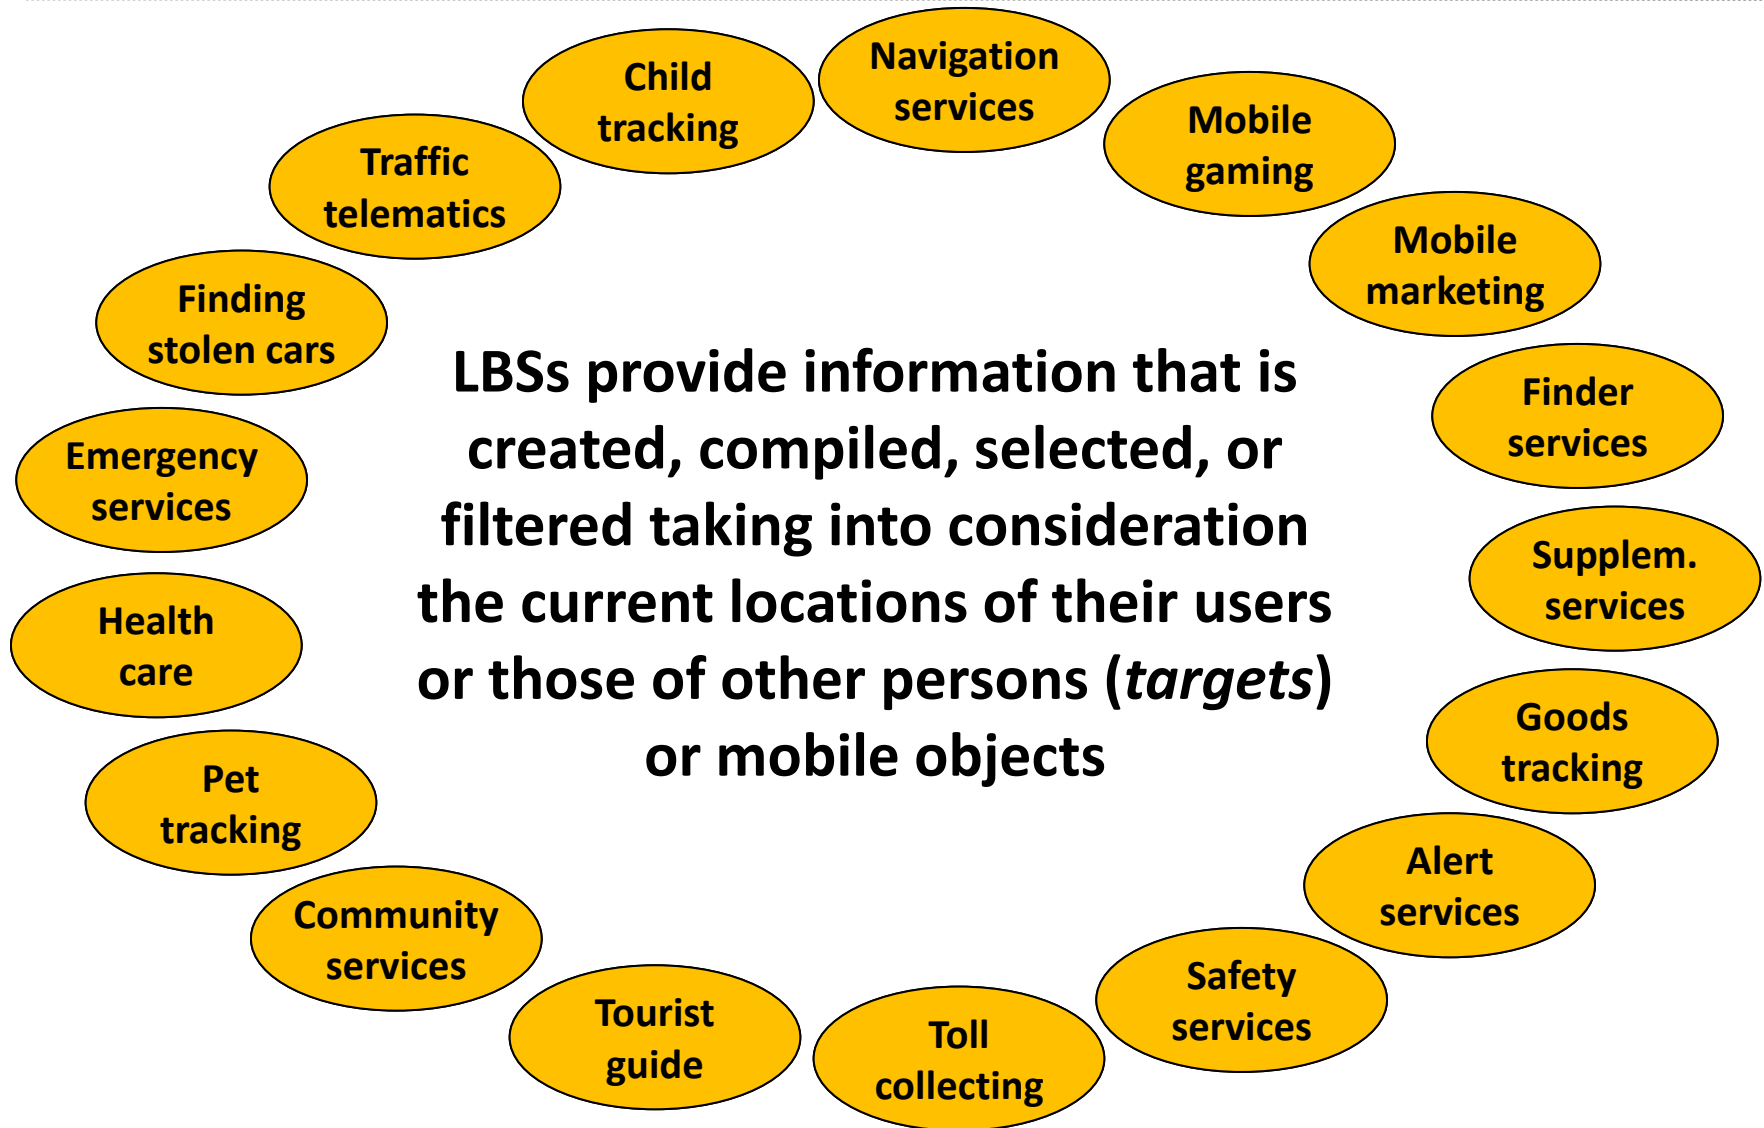

LBS – Relation to Other Areas

LBS as the intersection of several technologies (Brimicombe 2002):

- Internet
- Mobile Devices
- GIS

LBS – Application domains

Background: emergency services

- Persons calling an emergency response agency (e.g., police, fire) are unable to communicate their current location or they simply do not know it
 - Address of a caller can be easily determined when made over the fixed telephone network
 - But: rescue workers have serious problems locating emergency callers from mobile networks
 - emergency calls increasingly originate from mobile networks
-  Administrations in many countries oblige mobile operators to extend their networks for offering enhanced emergency services

Features of Enhanced Emergency Services

- *Selective routing*: routing of an emergency call to the *Public Safety Answering Point* (PSAP) that serves the geographical area the call originates from
- *Automatic Number Identification* (ANI): delivery and display of the emergency caller's telephone number
- *Automatic Location Identification* (ALI): determines the location (in terms of a street address) of an emergency caller

Examples

- Enhanced 911 (E-911) in the United States
- Enhanced 112 (E-112) in Europe
- Similar activities in Japan and Korea

E-911

- Passed by U.S. *Federal Communications Commission* (FCC) in 1996
- Phase 1
 - Derive a mobile caller's location from the coordinates of the serving cell site from where the emergency call has been made
 - Automatic Number Identification
 - Scheduled to be completed in April 1998
- Phase 2
 - Locate a caller accurately within 50 to 100m in 67% and 150 to 300m in 95% of all emergency calls
 - Required the operators to begin network enhancements not later than October 2001 and to finish them by December 2005
 - Operators were and still are faced with serious problems with the realization of Phase 2

<http://www.fcc.gov/911/enhanced/>

E-112

- Coordinated by the European *Coordination Group on Access to Location Information for Emergency Services* (CGALIES)
- CGALIES investigates and prepares for the introduction of enhanced emergency services in all countries of the EU
- Commitments for operators are less restrictive than in the U.S.
- No mandate, just recommendations defining several features of E-112
- No time schedule
- Operators are urged to locate emergency callers as accurately as possible

 <http://europa.eu/>

Role models

Classical approach, 1. Generation

Often: reactive, self-referencing, single-target, focus on outdoor applications, e.g. "Points of interest"

Terminal-centric approach

Classification Of Location-based Services

User/service-interaction:

1. Generation

User/target relationship:

Target/target relationship:

Direction of mapping:

Environment:

2. Generation

Terminal-centric approach

Positioning

- Outdoor: GPS or A-GPS
- Indoor: WLAN-Fingerprinting or Indoor-GPS
- Mainly terminal-based

Target of Positioning

- "Location Sharing" between different persons
- Central or Peer-to-Peer

User/Service-Interaction

- Proactive and asynchronous (e.g. Actions on entering certain zones)
- Tracking of targets necessary

➔ Terminal-based + Location Sharing + Proactivity

➔ Management of positions necessary

Position Management - Overview

- Location-based services are built upon *low-level* and *high-level* services
- *Low-level* functions are based directly on the positioning layer
- *High-level* functions have access to *low-level* functions. They are strategies to use low-level functions
- The application has access to all levels

[06KüpTre]

Position Management II

Architecture for Exchanging Position Updates (PUs) measured at a Mobile Terminal (MT)

- Position Tracker
 - Terminal-based positioning in short intervals
- Location Server
 - Configuration of the PU-Strategies
 - Polling of Position-information
- Position Monitor
 - Tracking and PUs following
 - ... a periodic method
 -a distance-based method
 -a zone-based method
 - Reply to poll-queries
- Communication over mobile network

[06KüpTre]

Position Management – Example Scenario

- Example represents generation 2 LBS
- The Location server acts as an intermediary between the mobile device and a LBS provider
- Mobile device receives instructions about the low-level position management function to apply
- Strategy is determined by the high-level functions

[06KüpTre]

Position Management – Low-level functions (1)

Low-level functions are strategies to transmit position updates to the location server...

Basic position queries are provide by this layer:

- **Polling:** The location server *polls* the current location from the mobile device. Can be performed periodic, on behalf of the application or on the location server.
- **Periodic position update:** The device triggers the updates after a certain time interval elapsed after the last position update.
- **Distance-based position update:** The mobile devices sends a position update if it has moved further away than a given threshold.
- **Zone-based position update:** Mobile devices sends a position update if it enters or leaves a predefined *update zone* (Polygon, Circle...)

Zone-based Update Jobs

- Objective:
 - Alert user when MTs enter or leave pre-defined zones
- Applications:
 - e.g. child tracking
- Efficiently monitor position on mobile terminal
- Definition of bounding polygon depends on used positioning technology (borderline tolerance)

Position Management – High-level functions

High-level functions are strategies on how to use the low-level functions...

- Number of required position updates (*low-level* function calls) should be **minimized** (transmission costs energy and bandwidth)

Possible *high-level* functions are:

- **Proximity detection:** Detect if a pair of mobile devices in a group approaches each other closer than a predefined *proximity distance*. Thus each mobile devices has a set proximate mobile devices.
- **Separation detection:** Detect automatically if two mobile devices in a given set have a larger distance than a predefined *separation distance*.
- **k-nearest neighbors:** Retrieve the *k* nearest other mobile devices
- **Clustering:** Is there a cluster of *k* targets within a certain area?

High-level functions – Proximity Detection (1)

- Objective:
 - Alert user when distance among MTs of targets gets below distance threshold C
- Applications:
 - Buddy Tracking, Mobile Gaming, Dating Services, Fleet Management,...

- How to track Bob and Eva without exchanging too many messages over the air-interface?

High-level functions – Proximity Detection (2)

- Let $dist(t_i, t_j)$ denote the geographic distance between t_i and t_j
- Proximity detection is implemented using the predefined constants:
 - Proximity distance d_p : Proximity for devices closer than d_p **must** be detected
 - borderline distance b : Proximity for devices closer than $d_p + b$ **may** be detected

- Requirements for proximity detection:
 - If $dist(t_i, t_j) < d_p$: Proximity **must** be detected
 - If $d_p \leq dist(t_i, t_j) \leq d_p + b$: Proximity **may** be detected
 - If $d_p + b < dist(t_i, t_j)$: Proximity **must not** be detected

High-level functions – Proximity Detection (3)

Proximity Detection with the **Static Circles Strategy**:

- The location server stores the last position fix c_i for each device i
- For each c_i a circle with radius $b/2$ is defined
- The mobile devices performs a **zone-based position update** if it leaves this circle
- $spd(t_i, t_n) = dist(t_i, t_j) - r_i - r_j$: smallest possible distance
- Non-proximate devices for a given device i are stored in the set $T_{p,i}$
- Algorithm if a mobile device t_i provides a fresh position fix p_i :

```
for n in  $T_{p,i}$ :
    if  $spd(t_i, t_n) < d_p$  then
         $p_n \leftarrow PositionUpdateRequest(n)$ 
        if  $dist(p_i, p_n) < d_p$  then
            raise proximity_alert
             $T_{p,i} \leftarrow T_{p,i} - n$ 
    else
        continue
```

High-level functions – Proximity Detection (4)

- The smallest possible distance would suffice for a classification as proximate devices...
- ... but after the position update from p_j we know they are not close enough
- **Question:** Which size should the new detection circle have?

- **Disadvantage:** Very distant devices perform a zone-based position update if they leave their circle
- **Possible Optimization:** Choose circles with a radius that corresponds to $spd(t_i, t_n) - d_p = r_i$ (Assumes that $d_p < spd(t_i, t_n)$)
→ Both circles are separated by a distance of d_p which guarantees that proximity is detected!

High-level functions – Proximity Detection (5)

Proximity Detection with the **Stripes Strategy (zone based updating)**:

- Establish a stripe of infinite length between two targets
- Width corresponds to the proximity distance threshold d_p
- If one target crosses the stripe a PU is performed by both targets
- Number of globally needed stripes is $n*(n-1)/2$
- Could lead to a scalability problem

Amir et al 2004

High-level functions – Proactive k-Nearest-Neighbors

- Objective:
 - Efficiently find k nearest neighbors for a given MT
- Simple approach:
 - Continuous position updates
 - Calculate distance between point i and all other points j ($j \neq i$)
- Better approach:
 - Use voronoi diagrams
 - Send position update only when entering / leaving a voronoi cell
- For $k > 1$: Higher order voronoi diagrams

Challenges for future LBS

- Positioning
 - Higher availability of positioning services
 - Standardized technologies for indoor positioning
 - Positioning handover
- LBS Middleware
 - Low level position management: exchange of position data between GPS device and server
 - High level position management: correlation of position data of several targets
- Privacy protection
 - Anonymization
 - Privacy policies
 - Mechanisms for reducing peer-group pressure
